Magnetic Flux, Flux Density & Flux Linkage

Magnetic Flux Density

- The strength of a magnetic field is defined by the density of the magnetic field lines, or **magnetic flux density**, at that point
 - Magnetic flux density is defined by the symbol B
 - It is measured in **Tesla** (T)
- Rearranging the equation for magnetic force on a wire, the magnetic flux density is defined by the equation:

$$B = \frac{F}{IL}$$

- Where:
 - B = magnetic flux density (T)
 - F = magnetic force on a current-carrying wire (N)
 - I = current (A)
 - L = length of the wire (m)
- For reference, the Earth's magnetic flux density is around 0.032 mT and an ordinary fridge magnet is around 5 mT
- The magnetic flux density is sometimes referred to as the **magnetic field strength**

Magnetic Flux

- Magnetic flux is a quantity which signifies how much of a magnetic field passes **perpendicularly** through some area
- For example, the amount of magnetic flux through a rotating coil will vary as the coil rotates in the magnetic field
 - It is a maximum when the magnetic field lines are **perpendicular** to the coil area
 - It is at a minimum when the magnetic field lines are **parallel** to the coil area
- The **magnetic flux** is defined as:

The product of the magnetic flux density and the cross-sectional area perpendicular to the direction of the magnetic flux density

- Magnetic flux is defined by the symbol Φ (greek letter 'phi')
- It is measured in units of **Webers (Wb)**
- Magnetic flux can be calculated using the equation:

$$\Phi = BA$$

- Where:
 - Φ = magnetic flux (Wb)
 - B = magnetic flux density (T)
 - A = cross-sectional area (m^2)

The magnetic flux is maximised when the magnetic field lines and the area through which they are passing through are perpendicular

- When magnetic flux is not completely perpendicular to the area A , then the component of magnetic flux density B perpendicular to the area is taken
- The equation then becomes:

$$\Phi = BA \cos(\theta)$$

- Where:
 - θ = angle between magnetic field lines and the line **perpendicular** to the plane of the area (often called the normal line) (degrees)

The magnetic flux increases as the angle between the field lines and the normal decreases

- This means the magnetic flux is:
 - **Maximum** = BA when $\cos(\theta) = 1$ therefore $\theta = 0^\circ$. The magnetic field lines are perpendicular to the plane of the area
 - **Minimum** = 0 when $\cos(\theta) = 0$ therefore $\theta = 90^\circ$. The magnetic fields lines are parallel to the plane of the area
- An e.m.f is induced in a circuit when the magnetic flux linkage changes with respect to time
- This means an e.m.f is induced when there is:
 - A changing magnetic flux density B
 - A changing cross-sectional area A
 - A change in angle θ

Magnetic Flux Linkage

- The **magnetic flux linkage** is a quantity commonly used for solenoids which are made of N turns of wire
- The flux linkage is defined as:

The product of the magnetic flux and the number of turns of the coil
- It is calculated using the equation:

$$\text{Flux linkage} = \Phi N = BAN$$

- Where:
 - Φ = magnetic flux (Wb)
 - N = number of turns of the coil
 - B = magnetic flux density (T)

- A = cross-sectional area (m^2)

Your notes

- The flux linkage ΦN has the units of **Weber turns (Wb turns)**

Worked Example

An aluminium window frame has a width of 40 cm and length of 73 cm as shown in the figure below

The frame is hinged along the vertical edge AC. When the window is closed, the frame is normal to the Earth's magnetic field with magnetic flux density $1.8 \times 10^{-5} \text{ T}$

Calculate the magnetic flux through the window when it is closed

Answer:

Step 1: Write out the known quantities

$$\text{Cross-sectional area, } A = 40 \text{ cm} \times 73 \text{ cm} = (40 \times 10^{-2}) \times (73 \times 10^{-2}) = 0.292 \text{ m}^2$$

$$\text{Magnetic flux density, } B = 1.8 \times 10^{-5} \text{ T}$$

Step 2: Write down the equation for magnetic flux

$$\Phi = BA$$

Step 3: Substitute in values

$$\Phi = (1.8 \times 10^{-5}) \times 0.292 = 5.256 \times 10^{-6} = 5.3 \times 10^{-6} \text{ Wb}$$

Worked Example

A solenoid of circular cross-sectional radius 0.40 m and 300 turns is placed perpendicular to a magnetic field with a magnetic flux density of 5.1 mT.

Determine the magnetic flux linkage for this solenoid.

Answer:

Step 1: Write out the known quantities

- Cross-sectional area, $A = \pi r^2 = \pi(0.4)^2 = 0.503 \text{ m}^2$
- Magnetic flux density, $B = 5.1 \text{ mT}$
- Number of turns of the coil, $N = 300$ turns

Step 2: Write down the equation for the magnetic flux linkage

$$\Phi N = BAN$$

Step 3: Substitute in values and calculate

$$\Phi N = (5.1 \times 10^{-3}) \times 0.503 \times 300 = 0.7691 = 0.8 \text{ Wb turns (2 s.f.)}$$

Examiner Tips and Tricks

Consider carefully the value of θ , it is the angle between the field lines and the line **normal** (perpendicular) to the plane of the area the field lines are passing through. If it helps, drawing the normal on the area provided will help visualise the correct angle.

Your notes

Magnetic Force on a Charged Particle

- The magnetic force on an isolated moving charged particle, such as a proton, is given by the equation:

$$F = BQv$$

- Where:
 - F = magnetic force on the particle (N)
 - B = magnetic flux density (T)
 - Q = charge of the particle (C)
 - v = speed of the particle (m s^{-1})
- This is the maximum force on the charged particle, when F , B and v are mutually perpendicular
 - Therefore if a particle travels **parallel** to a magnetic field, it will not experience a magnetic force
- Current is the rate of flow of **positive** charge
 - This means that the direction of the 'current' for a flow of negative charge (e.g. an electron beam) is in the opposite direction to its motion
- If the charged particle is moving at an angle θ to the magnetic field lines, then the size of the magnetic force F is given by the equation:

$$F = BQv \sin \theta$$

- This equation shows that:
 - The size of the magnetic force is **zero** if the angle θ is **zero** (i.e. the particle moves **parallel** to the field lines)
 - The size of the magnetic force is **maximum** if the angle θ is **90°** (i.e. the particle moves **perpendicular** to field lines)

Worked Example

A beta particle is incident at 70° to a magnetic field of flux density 0.5 mT, travelling at a speed of $1.5 \times 10^6 \text{ m s}^{-1}$.

Your notes

Copyright © Save My Exams. All Rights Reserved

Calculate:

- The magnitude of the magnetic force on the beta particle
- The magnitude of the maximum possible force on a beta particle in this magnetic field, travelling with the same speed

Answer:

Part (a)

Step 1: Write out the known quantities

- Magnetic flux density $B = 0.5 \text{ mT} = 0.5 \times 10^{-3} \text{ T}$
- Speed $v = 1.5 \times 10^6 \text{ m s}^{-1}$
- Angle θ between the flux and the velocity = 70°

Step 2: Substitute quantities into the equation for magnetic force on a charged particle

- A beta particle is an electron
- Therefore, the **magnitude** of electron charge $Q = 1.6 \times 10^{-19} \text{ C}$
- Substituting values gives:

$$F = BQv \sin \theta$$

$$F = (0.5 \times 10^{-3}) \times (1.6 \times 10^{-19}) \times (1.5 \times 10^6) \times \sin(70)$$

$$F = 1.1 \times 10^{-16} \text{ N}$$

Part (b)

Step 1: Write out the known quantities

- Magnetic flux density $B = 0.5 \text{ mT} = 0.5 \times 10^{-3} \text{ T}$
- Speed $v = 1.5 \times 10^6 \text{ m s}^{-1}$

Step 2: Determine the angle to the flux lines

- Angle θ between the flux and the velocity = 90° if the magnetic force is a maximum

Step 3: Substitute quantities into the equation for magnetic force on a charged particle

- The **magnitude** of electron charge $Q = 1.6 \times 10^{-19} \text{ C}$

- Substituting values gives:

$$F = BQv \sin \theta = BQv \text{ when } \sin 90 = 1$$

$$F = (0.5 \times 10^{-3}) \times (1.6 \times 10^{-19}) \times (1.5 \times 10^6)$$

$$F = 1.2 \times 10^{-16} \text{ N}$$

Your notes

Examiner Tips and Tricks

Remember not to mix this up with $F = BIL \sin \theta$!

- $F = BIL \sin \theta$ is the force on a current-carrying conductor
- $F = BQv \sin \theta$ is the force on an isolated moving charged particle (which may be inside a conductor)

Another super important fact to remember for typical exam questions is that the magnetic force on a charged particle is **centripetal**, because it **always acts at 90°** to the particle's velocity. You should practise using Fleming's Left Hand Rule to determine the exact direction!

Fleming's Left Hand Rule for a Charged Particle

- Fleming's left hand rule** can be used to determine the direction of the magnetic force on a moving charged particle in a magnetic field
 - The **First Finger** = direction of the magnetic field
 - The **Second Finger** = direction of conventional current (i.e. the velocity of a moving **positive charge**)
 - The **Thumb** = direction of the magnetic force
- Fleming's Left Hand Rule is illustrated in the image below:

Your notes

Fleming's Left Hand Rule shows the magnetic force, magnetic field and conventional current (flow of positive charge) are all perpendicular to each other

- Since this is represented in 3D space, sometimes the flow of charge, magnetic force or magnetic field could be directed into or out of the page, not just left, right, up and down
- The direction of the magnetic field **into** or **out of** the page in 3D is represented by the following symbols:
 - **Dots** (sometimes with a circle around them) represent the magnetic field directed **out** of the plane of the page
 - **Crosses** represent the magnetic field directed **into** the plane of the page

The magnetic field into or out of the page is represented by circles with dots or crosses

Your notes

- The way to remember this is by imagining an arrow used in archery or darts:
 - If the arrow is approaching **head-on**, such as out of a page, only the very tip of the arrow can be seen (a dot)
 - When the arrow is **moving away**, such as into a page, only the cross of the feathers at the back can be seen (a cross)

An Electron Moving in a Magnetic Field

- The maximum magnetic force on a moving charged particle is always perpendicular to its velocity
 - This means magnetic forces cause charged particles to move in a **circle**
- The **direction** of magnetic force on the charged particle can be determined using Fleming's Left Hand Rule
 - The image below shows an electron incident on a uniform magnetic field B directed into the page:

An electron moving to the left as shown is equivalent to a conventional positive charge or current moving to the right. Using Fleming's Left Hand Rule, the direction of the force can be determined

- According to Fleming's Left Hand Rule:
 - B is directed into the page, therefore the first finger should point **into** the page
 - The conventional current (or velocity of a **positive charge**) is directed to the **right** (because an electron is moving to the left), therefore the second finger should point to the **right**
 - Therefore, the force on the electron as shown by the thumb is initially **upwards** as it enters the magnetic field

Your notes

- The force due to the magnetic field is **always perpendicular to the velocity** of the electron
 - **Note:** this is equivalent to circular motion
 - Therefore, the magnetic force on a moving charge is a **centripetal force**
- The centripetal force is what keeps moving charges following a **circular** trajectory
- Examples of the direction of the magnetic force on positive and negative particles are:

The direction of the magnetic force F on positive and negative particles in a B field in and out of the page

- Fleming's Left Hand Rule can be used again to find the direction of the force, magnetic field and velocity
 - The key difference is that the second finger, representing current I (direction of positive charge), can now be used as the **direction of velocity v** of a **positive** charge

Examiner Tips and Tricks

The most important point when using Fleming's left hand rule is the direction of the **charge** (or **current** flow). This is always the direction of **positive** charge. Therefore, for electrons, or negatively charged ions, you should point your second finger for the current in the **opposite** direction to its motion.

Magnetic Force on a Current-Carrying Conductor

- A current-carrying conductor produces its own **magnetic field**
 - An **external magnetic field** will therefore exert a **magnetic force** on it
- A current-carrying conductor (eg. a wire) will experience the **maximum** magnetic force if the current through it is **perpendicular** to the direction of the magnetic flux lines
 - A simple situation would be a copper rod placed within a uniform magnetic field
 - When current is passed through the copper rod, it experiences a **force** which makes it accelerate

A copper rod moves within a magnetic field when current is passed through it

- The force F on a conductor carrying current I in a magnetic field with flux density B is defined by the equation

$$F = BIL \sin \theta$$

- Where:
 - F = magnetic force on the current-carrying conductor (N)
 - B = magnetic flux density of external magnetic field (T)
 - I = current in the conductor (A)

Your notes

- L = length of the conductor in the field (m)
- θ = angle between the conductor and external flux lines (degrees)
- This equation shows that the magnitude of the magnetic force F is **proportional** to:
 - Current I
 - Magnetic flux density B
 - Length of conductor in the field L
 - The sine of the angle θ between the conductor and the magnetic flux lines

Magnitude of the force on a current carrying conductor depends on the angle of the conductor to the external B field

- The **maximum** force occurs when $\sin \theta = 1$
 - This means $\theta = 90^\circ$ and the conductor is **perpendicular** to the B field
 - This equation for the magnetic force now becomes:

$$F = BIL$$

Your notes

- The **minimum** force (0) is when $\sin \theta = 0$
 - This means $\theta = 0^\circ$ and the conductor is **parallel** to the B field
- It is important to note that a current-carrying conductor will experience **no** force if the current in the conductor is parallel to the field

Worked Example

A current of 0.87 A flows in a wire of length 1.4 m placed at 30° to a magnetic field of flux density 80 mT.

Calculate the force on the wire.

Answer:

Step 1: Write down the known quantities

- Magnetic flux density, $B = 80 \text{ mT} = 80 \times 10^{-3} \text{ T}$
- Current, $I = 0.87 \text{ A}$
- Length of wire, $L = 1.4 \text{ m}$
- Angle between the wire and the magnetic flux lines, $\theta = 30^\circ$

Step 2: Write down the equation for the magnetic force on a current-carrying conductor

$$F = BIL \sin \theta$$

Step 3: Substitute in values and calculate

$$F = (80 \times 10^{-3}) \times (0.87) \times (1.4) \times \sin(30) = 0.04872 = 0.049 \text{ N (2 s.f.)}$$

Examiner Tips and Tricks

Remember that the direction of current is the flow of **positive** charge (i.e. conventional current) and this is in the **opposite direction** to the flow of electrons (i.e. electron flow)!

Fleming's Left Hand Rule for a Current-Carrying Conductor

- Fleming's Left Hand Rule was previously used to determine the direction of the magnetic force on a moving **charged particle** in a magnetic field
- It can also be used to determine the direction of the magnetic force on a **current-carrying conductor** in a magnetic field
 - This is because inside a conductor (e.g. a wire) there are **many** charged particles flowing as a current

- As a reminder, the image representing Fleming's Left Hand Rule is shown below:

Fleming's Left Hand Rule. Remember, current is the flow of conventional current (i.e. positive to negative)

- Using the conventional symbols representing vectors like magnetic flux density B and force F that go into the page (arrows) or out of the page (dots) we can apply Fleming's Left Hand Rule to problems in 3D

Worked Example

A current flows perpendicularly to a uniform magnetic field as shown in the diagram below.

As a result, the conductor carrying the current experiences a magnetic force, F .

Determine the direction of the current flowing in the conductor.

Answer:

Step 1: Apply the instructions for Fleming's Left Hand Rule

- Using Fleming's Left Hand Rule for the quantities given:
First finger is the magnetic field, B = into the page (or screen!)
Thumb is the direction of the magnetic force F = vertically downwards

Step 2: Determine the direction of the conventional current

- The first finger should be pointing into the page (or screen!) along the direction of the field
- Rotating the entire hand allows the thumb to point downwards, along the direction of force
- The second finger should be pointing towards the left of the page (or screen!)
- This is the direction of conventional current in the wire, i.e., from **right to left**

Copyright © Save My Exams. All Rights Reserved

Examiner Tips and Tricks

You will certainly need to apply Fleming's Left Hand Rule in your examination, at some point, whenever there is a current or charge flowing in a magnetic field. Remember, it is used to give the **direction** of either the magnetic force F , the magnetic field B , or the conventional current (or flow of positive charge) I .

As ever, you will gain more confidence twisting your arm in funny positions with three fingers at right-angles the more questions you practise: the more, the better!

Your notes

Induced E.M.F in a Moving Coil

- Electromagnetic induction is a phenomenon which occurs when an e.m.f is induced when a conductor moves through a magnetic field
- If there is a change in **magnetic flux** Φ or magnetic flux linkage $N\Phi$
 - **Mechanical work** (from moving the conductor in the field) is transformed into **electrical energy**
- Therefore, if attached to a complete circuit, a current will be induced in the conductor
- This is known as **electromagnetic induction** and is defined as:

The process in which an e.m.f is induced in a closed circuit due to changes in magnetic flux (linkage)

- This can occur either when:
 - A conductor cuts through a **magnetic field**
 - The magnetic flux (linkage) through a coil changes, e.g. becomes more or less dense, or changes direction
- Electromagnetic induction is used in:
 - Electrical **generators** which convert mechanical energy to electrical energy
 - **Transformers** which are used in electrical power transmission
- This phenomenon can easily be demonstrated with a magnet and a coil, or a wire and two magnets

Relative Motion between a Coil and a Magnet

- When a coil is connected to a sensitive voltmeter, a bar magnet can be moved in and out of the coil to induce an e.m.f in the coil

Your notes

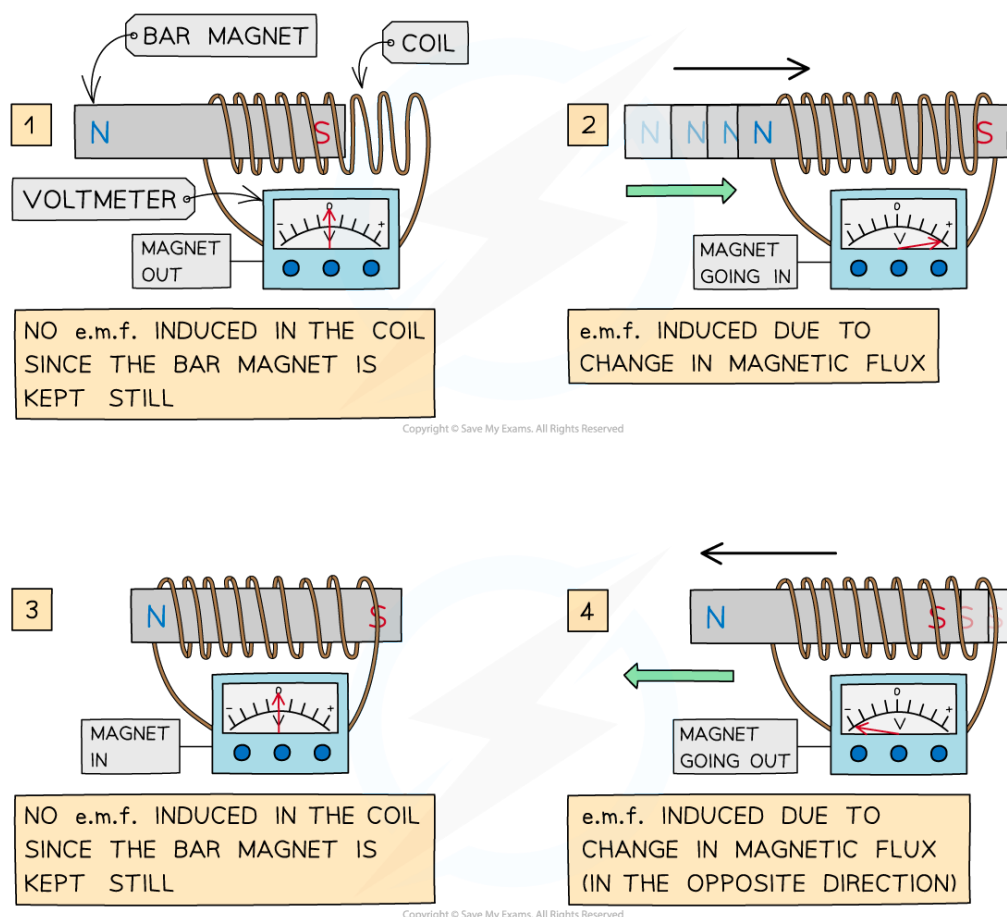

A bar magnet is moved through a coil connected to a voltmeter to induce an e.m.f

The observations are:

- When the bar magnet is **not moving**, the voltmeter shows a **zero reading**
 - When the bar magnet is held still inside, or outside, the coil, the rate of change of flux is zero, so, there is **no e.m.f induced**
- When the bar magnet begins to move inside the coil, there is a reading on the voltmeter
 - As the bar magnet moves, its magnetic field lines 'cut through' the coil, generating a **change in magnetic flux** ($\Delta\Phi$)
 - This induces an **e.m.f** within the coil, shown momentarily by the reading on the voltmeter
- When the bar magnet is taken back out of the coil, an e.m.f is induced in the **opposite direction**
 - As the magnet changes direction, the direction of the current changes
 - The voltmeter will momentarily show a reading with the opposite sign
- Increasing the **speed** of the magnet induces an e.m.f with a **higher magnitude**
 - As the speed of the magnet increases, the rate of change of flux increases
- The direction of the electric current, and e.m.f, induced in the conductor is such that it **opposes** the change that produces it

Your notes

An e.m.f is induced only when the bar magnet is moving through the coil

- Factors that will increase the induced e.m.f are:
 - Moving the magnet **faster** through the coil
 - Adding more **turns** to the coil
 - Increasing the **strength** of the bar magnet

Rotating Coils

- When a coil rotates in a uniform magnetic field, the **magnetic flux** through the coil will vary as it rotates
- Therefore, since the flux linkage through the coil also varies, this will induce an e.m.f that also varies
 - The maximum e.m.f is when the coil **cuts through** the most field lines
 - The varying e.m.f induced is called an **alternating voltage**

Your notes

Even though the flux linkage through the coil is maximum when $\theta = 0^\circ$, the change in flux linkage is minimal as the coil rotates, so the induced e.m.f is a minimum. The opposite is true when $\theta = 90^\circ$

- Increasing the coil's frequency of rotation increases:
 - The **frequency** of the alternating voltage
 - The **amplitude** of the alternating voltage

Induced E.M.F between Linked Coils

- An e.m.f can be induced in a coil when there is a change of current in another coil linked with this coil
 - This is what happens in a **transformer**

Transformers

- A transformer is a device that works by the principles of electromagnetic induction
- It changes high alternating voltages at low current to low alternating voltage at high current, and vice versa
- A transformer is made up of:
 - A primary coil
 - A secondary coil
 - An iron core
- The primary and secondary coils are wound around the soft iron core
 - The soft iron core is necessary because it creates **flux linkage** between the primary and secondary coils
 - Soft iron is used because it can easily be magnetised and demagnetised

Coils are magnetically linked, through their combined magnetic flux linkage, using a soft iron core

- In the primary coil, an alternating current producing an alternating voltage is applied
 - This creates an **alternating magnetic field** inside the iron core and therefore a changing magnetic flux linkage
- A changing magnetic field passes through to the secondary coil through the iron core

- This results in a changing magnetic flux linkage in the secondary coil and from Faraday's Law, an **e.m.f is induced**
- An e.m.f produces an alternating output voltage from the secondary coil
- The output alternating voltage is at the **same** frequency as the input voltage

Worked Example

When connected to a DC power supply, the primary coil of a transformer becomes an electromagnet.

Describe the changes which take place inside the secondary coil of a transformer when DC current in the primary coil is:

- a) Switched on
- b) Remains on
- c) Switched off

Part (a)

Step 1: Describe the creation of an electromagnet

- When current is switched on a magnetic field is produced around the primary coil

Step 2: Describe the change in magnetic flux linkage and induced e.m.f

- Magnetic flux is linked to the secondary coil
- Changing magnetic flux through the secondary coil induces an e.m.f in it
- This causes a current to flow (momentarily)

Part (b)

Step 1: Describe the non-change in magnetic flux linkage

- While the current in the primary coil remains on, there is no change in magnetic flux linkage through the secondary coil

Step 2: Describe the effect on induced e.m.f and current

- Therefore, the induced e.m.f (and therefore, the current in it) reduces to zero

Part (c)

Step 1: Describe the electromagnet 'switching off'

- When current is switched off the primary coil is no longer an electromagnet
- Therefore, the magnetic field around it vanishes

Step 2: Describe the change in magnetic flux linkage and induced e.m.f

- Magnetic flux is no longer linked to the secondary coil
- As the current switches off, changing magnetic flux through the secondary coil (as it reduces to zero) induces an e.m.f in **the opposite direction** to part (a)
- A current (momentarily) flows in **the opposite direction** to part (a)

Examiner Tips and Tricks

Explaining the link in e.m.f in both sets of coil in a transformer are very common exam questions. Make sure you've mentioned **every** point, including the words '**change**' in flux linkage and **induced** e.m.f. You must be specific with your terminology for full marks.

Your notes

Faraday and Lenz's Law

Faraday's Law

- Faraday's Law connects the **rate** of change of flux linkage with induced e.m.f
- It is defined in words as:

The magnitude of the induced e.m.f is directly proportional to the rate of change of magnetic flux linkage

- Faraday's Law as an equation is defined as:

$$\varepsilon = \frac{\Delta(N\Phi)}{\Delta t}$$

- Where:
 - ε = induced e.m.f (V)
 - $\Delta(N\Phi)$ = change in flux linkage (Wb turns)
 - Δt = time interval (s)
- If the interval of time becomes very small (i.e., in the limit of $\Delta t \rightarrow 0$) the equation for Faraday's Law can be written as:

$$\varepsilon = \frac{d(N\Phi)}{dt}$$

Lenz's Law

- Lenz's Law is used to predict the **direction** of an induced e.m.f in a coil or wire
- Lenz's Law is summarised below:

The induced e.m.f is set up in a direction to produce effects that oppose the change causing it

- Lenz's Law can be experimentally verified using:
 - A bar magnet
 - A coil of wire
 - A sensitive ammeter

Your notes

Lenz's law can be verified using a coil connected in series with a sensitive ammeter and a bar magnet

- A known pole (either north or south) of a bar magnet is pushed into the coil
 - This induces an e.m.f in the coil
 - The induced e.m.f drives a current (because it is a complete circuit)
- Lenz's Law dictates:
 - The direction of the e.m.f, and hence the current, must be set up to **oppose** the incoming magnet
 - Since a **north pole** approaches the coil face, the e.m.f must be set up to create an induced **north pole**
 - This is because two north poles will **repel** each other
- The direction of the current is therefore as shown in the image above
 - The direction of current can be verified using the right hand grip rule
 - Fingers curl around the coil in the direction of current and the thumb points along the direction of the flux lines, from north to south
 - Therefore, the current flows in an anti-clockwise direction in the image shown, in order to induce a north pole opposing the incoming magnet

Combining Lenz's Law and Faraday's Law

- Combining Lenz's Law into the equation for Faraday's Law is written as:

$$\varepsilon = - \frac{d(N\Phi)}{dt}$$

Your notes

- The **negative sign** represents Lenz's Law
 - This is because it shows the induced e.m.f $\mathcal{E}$ is set up in an '**opposite direction**' to oppose the changing flux linkage
- This equation also shows that the **gradient** of the graph of magnetic flux (linkage) against time, $\frac{\Delta(N\Phi)}{\Delta t}$ represents the **magnitude** of the induced e.m.f
 - Note: the negative sign means if the gradient is **positive**, the induced e.m.f is **negative**
 - This is again due to Lenz's Law, which says the e.m.f is set up to **oppose** the effects of the changing flux linkage

Worked Example

A small rectangular coil contains 350 turns of wire. The longer sides are 3.5 cm and the shorter sides are 1.4 cm.

The coil is held between the poles of a large magnet so that it can rotate about an axis through its centre. The magnet produces a uniform magnetic field of flux density 80 mT between its poles. The coil is positioned horizontally and then turned through an angle of 90° in a time of 0.18 s.

Calculate the magnitude of the average e.m.f induced in the coil.

Answer:

Step 1: Write down the known quantities

- Magnetic flux density, $B = 80 \text{ mT} = 80 \times 10^{-3} \text{ T}$
- Area, $A = 3.5 \times 1.4 = (3.5 \times 10^{-2}) \times (1.4 \times 10^{-2}) = 4.9 \times 10^{-4} \text{ m}^2$
- Number of turns, $N = 350$
- Time interval, $\Delta t = 0.18 \text{ s}$

Step 2: Write out the equation for Faraday's law:

$$\mathcal{E} = \frac{\Delta(N\Phi)}{\Delta t}$$

Your notes

Step 3: Write out the equation for the change in flux linkage:

- The number of turns N and the coil area A stay constant
- The flux through the coil changes as it rotates
- Therefore, the change in flux linkage can be written as:

$$\Delta(N\Phi) = NA(\Delta B)$$

Step 4: Determine the change in magnetic flux linkage

- The initial flux through the coil is zero (flux lines are parallel to the coil face)
- The final flux through the coil is 80 mT (flux lines are perpendicular to the coil face)
- This is because the coil begins horizontally in the field and is rotated 90°
- Therefore, the change in flux linkage is:

$$\Delta(N\Phi) = NA(\Delta B) = 350 \times (4.9 \times 10^{-4}) \times (80 \times 10^{-3}) = 0.014 \text{ Wb turns}$$

Step 5: Substitute change in flux linkage and time into Faraday's law equation:

$$\mathcal{E} = \frac{0.014}{0.18} = 0.076 \text{ V}$$

Examiner Tips and Tricks

The 'magnitude' of the e.m.f just means its size, rather than its direction. This is often what is required in exam questions, so the minus sign in Lenz's law is not necessarily required in calculations. However, you may be expected to explain the significance of the negative sign in the equation, so be prepared to interpret it as an expression of Lenz's Law!

Remember that 'd' and the greek letter delta, ' Δ ', simply mean 'change in'.
